

1. Project Planning & Documentation

- **Requirement Analysis:** Ensure that initial requirements are well-documented
- **System Design Documentation:** Check for entity-relationship diagrams (ERDs), data flow diagrams (DFDs), and other design artifacts.

2. Functionality Implementation

- **Core Features:** Confirm that the main modules or features making up 30% of the system's planned functionality have been developed.
- **Navigation & User Interface:** Assess if the user interface is user-friendly and functional for the parts that have been implemented.
- **Input & Output Validation:** Check that proper data validation and error handling have been added for implemented components.
- **Basic CRUD Operations:** Verify that basic Create, Read, Update, and Delete operations are functioning as expected.

3. Database Integration

- **Database Schema:** Ensure that the database schema is properly designed and matches the requirements of the implemented features.
- **Data Integrity:** Confirm that data integrity constraints (e.g., primary keys, foreign keys) are correctly implemented.
- **Sample Data:** Check if the database has been populated with sample data for testing purposes.

4. Code Quality & Standards

- **Readability:** Review code for readability, including the use of meaningful variable names and comments.
- **Modularity:** Check that code is modular, with functions and methods logically separated.
- **Adherence to Coding Standards:** Ensure that industry best practices and coding standards are followed.

5. Testing & Debugging

- **Basic Unit Testing:** Verify that basic unit tests have been written for the implemented features.

- **Bug Tracking:** Check if a system for tracking and resolving bugs has been established.

6. User Experience (UX)

- **Responsiveness:** Check that the user interface is responsive for different screen sizes, if applicable.
- **Basic Usability:** Evaluate the usability of the implemented features and ensure they align with user expectations.
